Bionics

One day in 1948, the Swiss engineer **George de Mestral** was cleaning his dog of burrs picked up on a walk when he realized how the hooks of the burrs clung to the fur. His realization led to the invention of **Velcro** -- and a multimillion-dollar industry.

Burdock → Velcro

What is Biomimetics/Biomimicry?

Biomimetics:

The study of the structure and function of biological systems as models for the design and engineering of materials.

Biomimicry: Innovation Inspired by Nature

--Janine Benyus

- Using natural processes as the model for agriculture and business.
- Advances in materials and medicine based on research into natural processes.

Lotus Effect

Hydrophobicity and self-clean

Comprehensive diagram illustrating the connection between roughness and self-cleaning: While on a smooth surface (left) dirt particles are only moved by the water droplet, on a rough surface (right) they adhere to the water droplet and are carried and washed away by the droplet while rolling down the surface.

The Lotus Effect. Water forms droplets on the tips of the epidermal protrusions and collects pollutants, dirt and small insects as it rolls off the leaf.

COOL SCHOOL: Dieter Gurtler discovered that the fastest fish aren't the most efficient, a principle he then applied to car design.

Octopus to Jet Engine

Eyes of Moth to Autoflex MARAG

(MothEye Anti-Reflective, Anti-Glare)

These compound eye structures have evolved to collect as much light as possible without reflection, in order to prevent moths being detected by night time predators. Applications include flat panel displays, touch screen interfaces, electroluminescent lamps and lenses for mobile phones and PDAs.

Autotype, one of the world's leading developers and manufacturers of film and chemical products, recently launched **a new anti-reflective, anti-glare film** inspired by the eye structure of night flying moths. Developed jointly by Autotype and the Fraunhofer Institute for Solar Energy in Germany, the new Autoflex film replicates the nano-structures found in the eyes of moths.

Researchers at INL are defining natural adhesive systems at the molecular scale and are exploring ways to recombine proteins to improve adhesives. Such new adhesives may more strongly bond to a wide range of materials and do so in an environmentally friendly and safe manner.

Sharkskin Effect

- ❖ Shark skin is very rough, in fact so rough that dried shark skin can be used as sanding paper.
- ❖ The skin is covered by little V-shaped bumps, made from the same material as sharks' teeth.
- ❖ The rough surface has been shown to reduce friction when the shark glides through water, which is why sharks are surprisingly quick and efficient swimmers.

mm

The groove structure of the shark scales

The U-shaped channels on a shark's skin generate tiny vortexes, bringing the water closer to the body and reducing drag. The large picture on the left shows a scanning electron microscope image of shark skin. ("Fizik, Teknoloji ve Olimpiyatlar" Physics, Technology and Olympics, *Bilim ve Teknik*, 77.) At the Sydney Olympics, all gold-medal-winning swimmers like the **Australian Ian Thorpe**, wore swimsuits with the same properties as shark skin. This important development led to a new sphere of business activity. Firms such as Speedo, Nike and Adidas, well known bathing suit manufacturers, hired many experts in the fields of biomechanics and hydrodynamics.

Swimsuits sharkskin inspired

Durch Kombination von Gewebefasern und einzigartige Nanotechnik spiegelt die anatomische Schwimmbewegung das Muskelsystem wider und erhöht die Muskelkoordination.

Maximale Körperbedeckung und das schnellste Material ergeben die optimale Silhouette für einen Schwimmzug. Exakte Vermessung von Elite-Schwimmern in wettbewerbsrelevanten Positionen gewährleistet eine perfekte Passform des Anzugs.

Das Fast Skin-Material ist die Haut eines Hai ohne nachempfundene, 3D-ähnliche Erhebungen und ein dichtere, körnigerer Druck des Materials sorgen für die Verringerung des Wasserwiderstandes. Der Körper gleitet geschmeidig durch das Wasser.

Die Armbandsanteile sind mit einem speziellen Trichter-Gewebe versehen, damit der Schwimmer die Wasserströmung „greifen“ und besser spüren kann.

whale flipper

Translating whale power into wind power, biomechanist Frank Fish helped design turbine blades with tubercles (nodules) inspired by the flipper of a humpback whale (left, from a deceased animal). The flipper's scalloped edge helps it generate force in tightly banked turns. The whale-inspired blades are being tested at the Wind Energy Institute of Canada (below) to see if they can make more power at slower speeds than conventional blades, and with less noise.

Humpback whale

Large vortices are formed behind the troughs along the leading edge whereas flow behind the tubercles forms straight streamlines. The effect of these flow patterns induced by the tubercles is to delay stall.

Mother-of-Pearl Inspires Lightweight Building Materials

Mother-of-pearl, also called nacre, is composed of alternating layers of calcium carbonate (in a special crystal form called aragonite) and Lustrin-A protein. The combination of hard and elastic layers gives nacre remarkable toughness and strength, allowing the material to slide under compressive force.

Butterfly Mouthpart to Drinking Straw

Modern-day architects and engineers can gain much insight and inspiration by studying living things. This building, the **Swiss Re Tower in London**, resembles a microorganism called a **glass sponge**. By looking even deeper into biology, at the level of genes and DNA, civil engineers may be able to develop a completely new approach to their work. Using so-called **genetic algorithms**, they may be able to imitate the biological processes of genetic crossover, mutation and evolution in computer simulations to create optimized designs.

Honey Bird to GR7

Owls silently glide at night to catch their prey unawares, then suddenly swoop down. According to the findings of researchers at NASA's Langley Research Center in Virginia, an owl's flight feathers—unlike most birds, the flight feathers of whose have a sharp, clean edge—have soft fringes that decrease the turbulence, and thus the noise, of air as it flows over wing. Military designers hope that stealth airplanes can be made even stealthier by imitating the owl's wings. It is hoped that planes now invisible to radar will be completely silent.

(R. Meadows, "Designs from Life," Zooger, 1999.)

The shape of birds' wings is the determining factor in their ability to fly. Wings of fast-flying birds like the falcon, hawk, and swallow are long, narrow and pointed—features that have served as a guide to flight engineers.

Crickets inspire fine hair sensors

Adult crickets have around 1000 or more hairs, 100 to 1500 microns long on organs called **cerci**, which allows them to detect air movements down to 1mm/s or less, indicating the possible approach of predators. The high sensitivity comes about because the tilting hairs apply pressure to neurons at their bases, greatly enhanced by mechanical lever amplification.

Termite-inspired Air Conditioning Simply by Architecture

Green Building in Zimbabwe Modeled After Termite Mounds

Eastgate Centre, Harare, Zimbabwe

Air is continuously drawn from this open space by fans on the first floor. It is then pushed up vertical supply sections of ducts that are located in the central spine of each of the two buildings. The fresh air replaces stale air that rises and exits through exhaust ports in the ceilings of each floor. Ultimately it enters the exhaust section of the vertical ducts before it is flushed out of the building through chimneys.

The Eastgate Centre uses less than 10% of the energy of a conventional building its size. These efficiencies translate directly to the bottom line: Eastgate's owners have saved \$3.5 million alone because of an air-conditioning system that did not have to be implemented.

Toucan's Beak

The lightweight strength of the Toco Toucan's beak

The beak is mostly air: The beak has a hollow region in an interior region where the mechanical stresses were insignificant. The beak's interior is a highly organized matrix of stiff cancellous bone fibers that looks as if it was dipped into a soapy solution and dried, generating drum-like membranes that interconnect the fibers. The result is a solid "foam" of air-tight cells that gives the beak additional rigidity.

The bombardier beetle, power venom, and spray technologies

Bombardier Beetle defence mechanism :

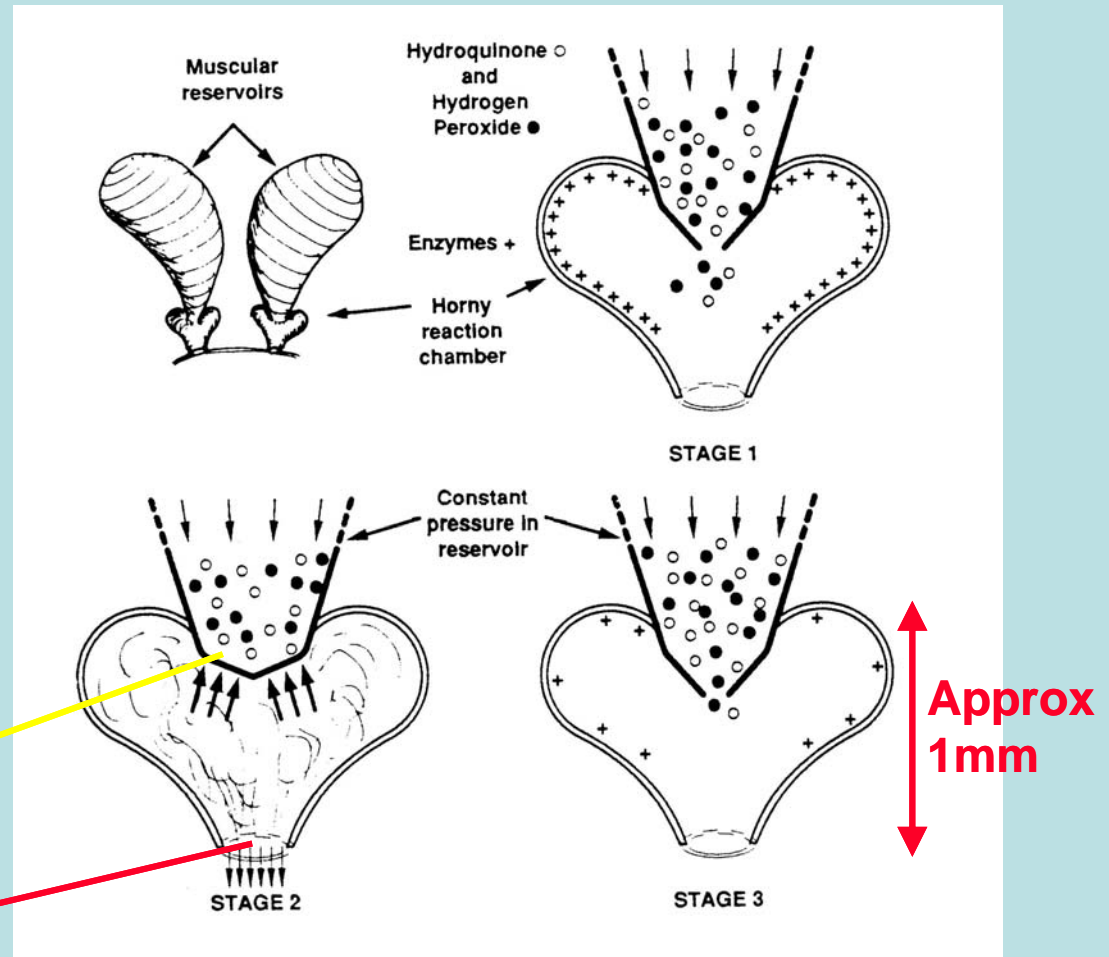

From work of Professor Tom Eisner of Cornell University : Eisner, T and Aneshansley, D. J, "Spray aiming in the bombardier beetle: Photographic evidence", *Proc. Natl. Acad. Sci. USA* Vol. 96, pp. 9705–9709, August 1999

- Experimental work by Eisner on Bombardier Beetle

Bombardier Beetle – Pulse combustion par excellence!

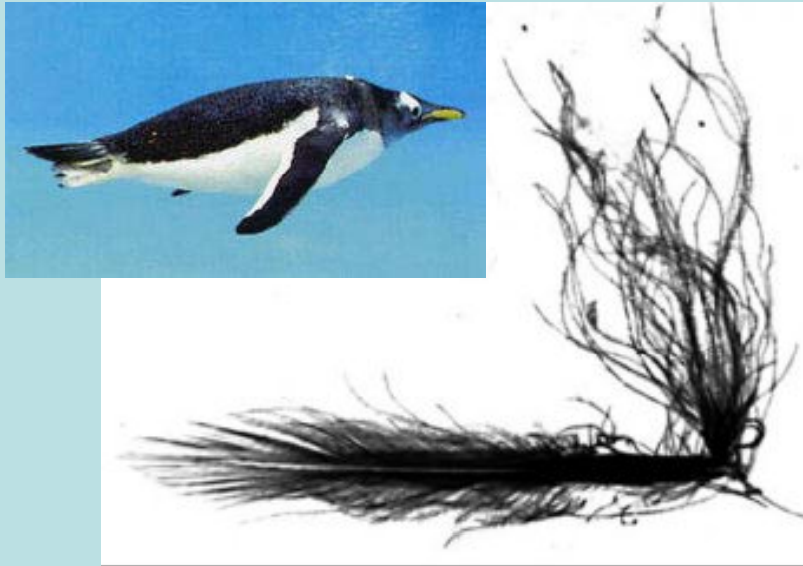

Fuel-inlet valve opened at low pressure, closed at high pressure. Exhaust-outlet at high pressure.....

.....but latest finding is of a sophisticated pressure release valve at outlet

The bombardier beetle, power venom, and spray technologies

- The bombardier beetle is inspiring designers of **engines**, **drug-delivery devices** and **fire extinguishers** to improve spray technologies.
- The bombardier beetle, found mainly in Africa and Asia, is remarkable in that it can fire a powerful jet of hot, toxic fluid to fight off predators such as birds and frogs. While the chemical reaction that makes the venom has been understood for some time, the actual power behind the venomous squirt, which can travel as far as 20cm, has been cause for speculation.

Penguin feather structure as excellent insulator

- They are compressed by the pressure of the water, they are bent and then jump back into shape like springs when the penguin leaves the water.
- When the penguin dives the air is pressed out of the feathers, the coat collapses and the penguin becomes thin and streamlined. When the penguin leaves the water again, the coat must inflate immediately.

Mollusk-inspired Fan: Energy Saver and Reduction of Noise

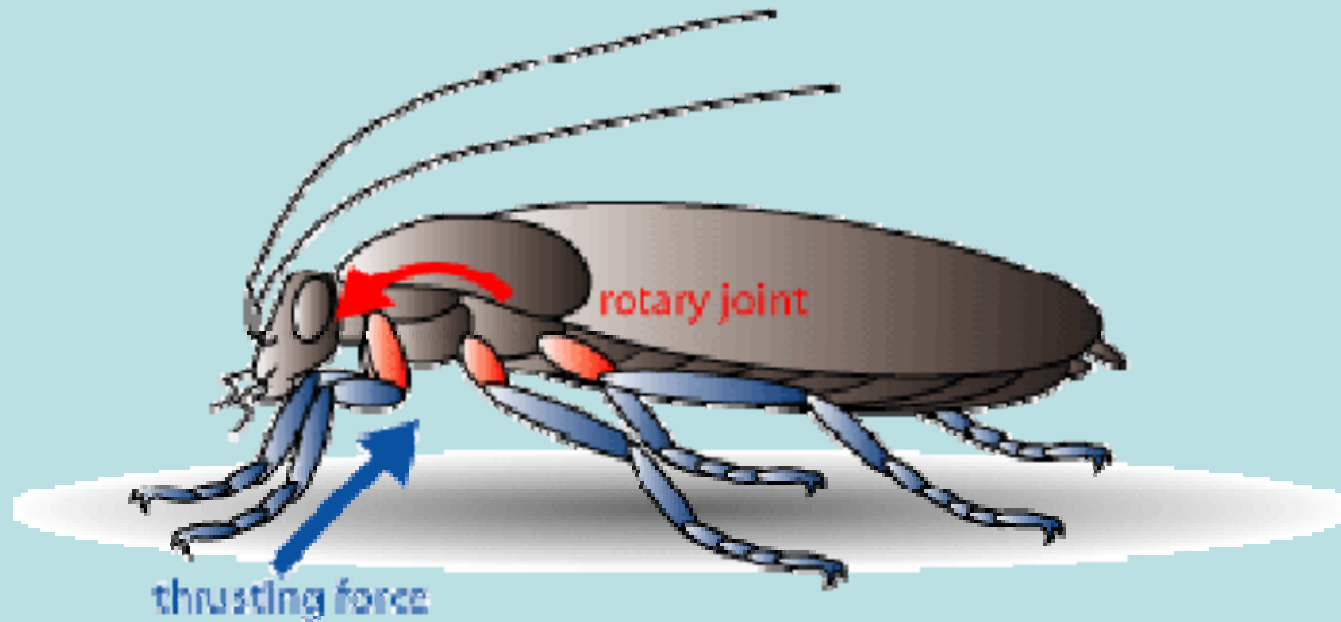

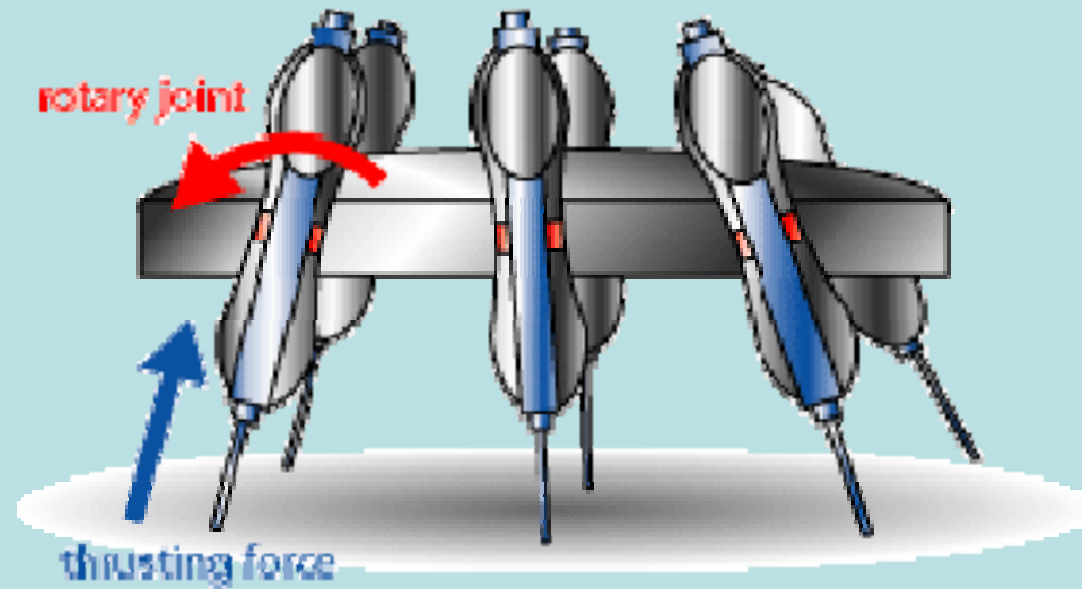

A three-dimensional logarithmic spiral is found in the shells of mollusks. Liquids and gases flow centripetally through these geometrically consistent flow forms with far less friction and more efficiency. Computational Fluid Dynamics and Particle Image Velocimetry tests showed the technology's streamlining effect can reduce energy requirements in fans and other rotors from between 10 and 85%, depending upon the application; the fan blade design also reduces noise by up to 75%.

PAX Scientific (USA)

Smart fabrics

- By carrying out research on the opening and closing of pine cones and the insulation layers of penguins, we have worked on the principles of design of a fabric which can be used to make responsive clothing, with transpirational properties based on the state of activity of the wearer.
- e.g. a soldier in the deserts around the Gulf will otherwise need few layers by day in the baking heat, but lots of layers by night in the chill of the sand.

Optical Camouflage

Optical Camouflage requires the use of clothing – in this case, a hooded jacket – made with a retro-reflective material, which is comprised by thousands of small beads that reflect light precisely according to the angle of incidence. A digital video camera placed behind the person wearing the cloak captures the scene that the individual would otherwise obstruct, and sends the data to a computer for processing.
