USSR: Single-Cell Protein Industry (U)

Summary

Information available as of 1 January 1984 has been used in this report. (U)

The Soviet single-cell protein (SCP) industry represents a major effort to support livestock production by producing a protein-rich feed supplement for animals. We estimate that the Soviets had the capacity to produce about 1.8 million metric tons of SCP in 1983 and that this will increase to about 2 million metric tons by 1985	_25 X 1
	25X1
Actual Soviet SCP production is probably considerably less than capac-	
ity because the Soviets have encountered delays in bringing newly constructed plants into full operation. As a result, we believe that the Soviets	
ets will probably not reach their goal of 2.3 million metric tons of SCP	
production in 1985, and probably will only reach 2 million metric tons	
in the late 1980s. Based on Soviet claims, 2 million metric tons of SCP	
would replace as much as 10 million metric tons of grain, about 5	_
percent of Soviet annual grain production. (S	25X1
2	25X1

Currently, the Soviets produce SCP from both cellulose- and petro-leum-based feedstocks. We believe, however, that any major expansion of the Soviet SCP industry will probably involve construction of plants using methanol, produced from natural gas, as the feedstock. Reports from European technical journals indicate that the Soviets plan to produce about 4 million metric tons of methanol-based SCP by 2000. (C)

increases the efficiency of Soviet feed rations and serves to reduce these grain import requirements. (C)

The Soviets began experimental production of cellulose-based SCP from hydrolyzed straw in 1936. A Soviet text book reports that by 1943 they had begun industrial production of SCP at two plants; they have continued to expand this cellulose-based portion of the industry since that time. In 1963 the All-Union Scientific Research Institute for Protein Synthesis began research on production of SCP from liquid paraffin obtained from crude oil. Experimental petroleum-based SCP production began at the Krasnodar Biochemical and Vitamin Preparation Combine in the late 1960s, and construction of six commercial-scale plants began in the early 1970s. The first of these petroleum-based plants began partial operation in 1975. (S

Soviet SCP plants are usually located near their sources of feedstocks. Many of the cellulose-based plants are in agricultural areas or are part of large paper or lumber mills. All Soviet petroleum-based SCP plants are located near petroleum refineries. (S

Processes and facilities at cellulose-based plants differ from those at petroleum-based SCP plants. The cellulose-based plants have a smaller capacity and also produce wood-based byproducts, such as furfural and lignin, in addition to cellulose-based SCP (sometimes referred to as fodder yeast by the Soviets). The more modern petroleum-based plants use a standardized process whose only product is SCP. SCP cultivated on petroleum feedstock is sometimes called protein-vitamin concentrate (BVK byelokovo-vitaminyy kontsentrat) by the Soviets.

(S

Cellulose-Based SCP

Process Flow. The production process for cellulosebased SCP begins with hydrolysis of either a solid feedstock, such as wood waste or corn cobs, or a liquid feedstock, such as waste liquor from the pulp and paper industry (figure 2). The feedstock is combined with dilute sulfuric acid and heated in a hydrolysis tank. When waste liquors are the feedstock steam hydrolysis is used, probably to remove sulfur dioxide. The hydrolysis step produces simpler carbohydrates that are more readily digested by the SCP organisms. After neutralization and purification the carbohydrates, along with air and mineral salts, are sent to a fermentation vessel where they are innoculated with yeast. Following fermentation the SCP is purified, dried, and bagged for shipment. (U)

A Soviet text on production of SCP states that feedstock equivalent to a metric ton of dry coniferous wood will yield about 230 kilograms of SCP. At some plants the carbohydrates are fermented to produce ethyl alcohol and the remaining mash is then used to grow the SCP. According to the Soviet text, this reduces the yield to 32 kilograms per metric ton of wood equivalent. (U)

Capacity Estimate. The methodology used to estimate Soviet cellulose-based SCP production capacity was developed by the Analytical Support Group, Directorate of Intelligence, CIA. This methodology is based on imagery and data from Soviet opensource literature and human sources. (S

We identified a distinctive piece of processing equipment, a large open-topped tank, at all but one of the 60 plants that produce cellulose-based SCP (figure 3). Although we could not determine the function of these tanks, the number of tanks at each plant appears to be proportional to the overall size of the plant. (S

For 15 of the plants, production capacity data are available from either open-source literature or human-source reporting. These data and the number of open-topped tanks at each plant provide a basis for a regression analysis to estimate total production capacity for the cellulose-based plants (figure 4). (See Appendix A for the number of tanks and reported capacity at each plant.) (S

The data used in the regression estimate were first screened for reliability and then weighted based on the year of the report, the reliability of the source, and a comparison of the reported capacity to the size of production facilities

addition, the plants were classified into two groups based on the availability of feedstock. The first group consists of plants with year-round access to feed materials and the second group consists of plants with seasonal access to feed materials. Our judgement of the availability of feedstock is based on the geographic location of each plant, its proximity to sources of feed materials, and the size of feed-material stockpiles. (S

Based on the regression analysis, we estimate the annual production capacity of the 59 SCP plants with open-topped tanks was about 915,000 metric tons in 1983.² The one additional operating Soviet plant, at Kirishi, has no open-topped tanks, but based on the size of its facilities compared to other cellulose-based SCP plants, we estimate that it has a capacity of about 25,000 metric tons per year.³ Therefore, we estimate total Soviet cellulose-based SCP production capacity in 1983 was about 940,000 metric tons. (S

We were unable to differentiate between those cellulose-based plants that produce SCP as a primary product and those which produce alcohol as a primary product and SCP as a byproduct. Nevertheless, we believe the plants for which we have capacity figures are sufficiently representative of the entire group that our estimate of overall capacity is valid. Although the inclusion of information about alcohol production in the regression analysis might have reduced the confidence interval width, there is no statistical indication that this would have substantially changed our estimate of production capacity. We believe the availability of the feedstock is the only significant variable, aside from the number of tanks, in the regression equation. (8 NF

Figure 4 Correlation of the Number of Open-Topped Tanks to Production Capacity at Soviet Cellulose-Based SCP Plants

- Reported capacity for plant with seasonal access to feedstocks.
- Reported capacity for plant with year-round access to feedstocks.
- ^a We have assumed that the production reported for the Leningrad plant, 18,000 tons a year, was garbled and that it was actually 1,800 tons a year.

Secret

Petroleum-Based SCP

Process Flow. The petroleum-based SCP process at Soviet plants uses normal paraffins (n-paraffins), obtained from crude oil during the petroleum refining process, as the growth media. Nutrient salts are mixed with n-paraffins to form a substrate. The substrate is then innoculated with yeast of the Candida genus and fermented. The yeast produced is

²The 90-percent confidence interval for cellulose-based SCP production is 754,000 to 1,076,000 metric tons. This excludes the capacity of the Kirishi plant. (S

We do not know why Kirishi does not have visible open-topped tanks. The tanks may be inside buildings or concealed by other equipment at the facility. (S

Secret

killed, purified, concentrated, and dried before being packaged for shipment (figure 5). Most of the process steps are concealed from view inside buildings, but the fermentation tanks and dryers are large, readily identifiable pieces of equipment that are constructed as separate structures. (S

Purification is a critical step in processing SCP because paraffins contain some benzopyrene, a carcinogenic hydrocarbon. Any benzopyrene in a feed additive is dangerous because it may be passed on to humans through the meat of the animals.

(C

Capacity Estimate. The methodology used to estimate the capacity of the eight Soviet petroleumbased SCP plants is based on imagery analysis and

literature. From imagery we can identify the plants and count the number of fermentation tanks at each (figure 6). (S

Comparison of the number of these tanks at each plant with the plant's reported capacity indicates that each tank has a production capacity of 10,000 metric tons of SCP per year. At Gor'kiy the number of tanks multiplied by 10,000 tons per year equals the reported capacity. The layouts of the Angarsk and Kremenchug plants strongly suggest that, when complete, the number of tanks multiplied by 10,000 tons will equate to their reported capacity. The capacities indicated by the numbers of tanks observed at Polotsk, Ufa and Volgograd differ slightly from the reported capacities for these plants, probably because the Soviets are expanding these three plants beyond their reported original design capacity. No precise capacity figure for Kirishi has been reported

by the Soviets. Construction at Mozyr has not progressed sufficiently to determine the number of tanks planned. (See Appendix B for the number of tanks and reported capacity of each plant.) (S	Soviet plans call for production of 2.3 million tons of SCP in 1985, but it is unlikely that the Soviets will reach this goal. We believe Soviet production capacity for both cellulose-based and petroleum-	25X1

This would equal about 5 percent of Soviet average annual grain production. (s	25X1 25X1 25X1

In addition, the problems associated with the petroleum-based process may discourage construction of additional petroleum-based plants. We believe it is likely that any major expansion of Soviet SCP production will involve construction of plants using a new process, based on methanol produced from natural gas. Existing petroleum-based plants could also be converted to produce methanol-based SCP. (S

Expanding Soviet production of natural gas makes methanol-based SCP an attractive alternative for the Soviet Union. A European technical journal reported the Soviets plan to use 600,000 metric tons of methanol per year as an SCP feedstock by 1990 and 6 million metric tons by 2000. Based on feedstock-to-output ratios for a Western methanol-based SCP plant, this would equate to a methanol-based SCP production of about 400,000 metric tons in 1990 and about 4 million metric tons in 2000. Although we doubt the Soviets will be able to meet the goals, the large increases in SCP capacity planned indicate continuing Soviet belief in the utility of SCP to supplement grain production (figure 7). (S

Soviet licensing of methanol-based processing technology or purchase of turnkey plants would be a key indicator of their intentions to develop methanol-based SCP production. The Soviets could also choose to use domestic technology and equipment. In this case imagery would likely provide the initial indications of a Soviet program to develop methanol-based SCP. (S

Solikamsk Cellulose and Paper Combine 591446N 0564002E	Sulfite liquor	Year-round	8	
Sovetsk Cellulose SCP Plant 550530N 0215340E	Wood waste or sulfite liquor	Year-round	3	
Syas'stroy Cellulose Combine 600745N 0323345E	Probably sulfite liquor	Year-round	3	
Syktyvkar Cellulose SCP Plant Sloboda 614935N 0504350E	Wood waste	Year-round	12	28,000
Tallinn Cellulose Paper Combine Kingisepp 592533N 0244705E	Reportedly sulfite liquor	Year-round	4	
Tavda Wood Chemistry Plant 580425N 0651442E	Wood waste	Seasonal	9	
Tulun Alcohol Plant 543227N 1003542E	Wood waste	Seasonal	8	

(Continued)

Name (Alternate Names) Geographic Coordinates	Growth Media	Availability	Open- Topped Tanks	Reported Capacity ^a
Turinsk Cellulose Plant 580147N 0634315E	Wood waste or sulfite liquor	Seasonal	3	
Volgograd Hydrolysis Plant 484015N 0442752E	Unidentified waste vegetation	Seasonal	13	
Volzhsk Paper Plant 555057N 0482256E	Wood waste	Year-round	11	21,000
Vyborg Cellulose and Paper Plant Sovetskiy 603243N 0284045E	Probably sulfite liquor	Year-round	1	
Yangiyul' Biochemical Plant 410615N 0690310E	Ambari-hemp tow, cotton-plant waste, rice hulls, wood waste	Seasonal	9	7,000
Zaporozhye Cellulose SCP Plant 474925N 0351302E	Wood waste	Seasonal	10	11,000
Zima Cellulose SCP Plant 535540N 1020439E	Wood waste	Year-round	8	

^a Capacities are given in metric tons per year.

This appendix is Secret

25X1

b This plant also produces SCP from petroleum.

 $^{^{\}rm C}$ This figure is probably incorrect. The more likely capacity of this plant is about 1,800 to 3,000 metric tons.

d One of the Sokol plants is also known as Sukhona.

Appendix B

Soviet Petroleum-Based SCP Plants

Name	Fermentation Tanks		Capacity ^a		Remarks
(Alternate Names) Geographic Coordinates	Complete	Under Construction	1983	1985	
Total	82	21	820,000	1,030,000	
Angarsk SCP Plant 522910N 1035830E	11	1	110,000	120,000	Design capacity of 120,000 tons reported in 1970.
Gor'kiy SCP Plant (Kstovo, Novogorskiy) 560635N 0440700E	7	0	70,000	70,000	Design capacity of 70,000 tons reported in 1974.
Kirishi SCP Plant 592935N 0320100E	9	0	90,000	90,000	This plant also produces SCP from wood waste.
Kremenchug SCP Plant 491055N 0332855E	8	2	80,000	100,000	Design capacity of 120,000 tons reported in 1980.
Mozyr SCP Plant 515434N 0291731E	0	5	0	50,000	Design capacity of 300,000 tons reported in 1978.
Polotsk SCP Plant (Novopolotsk) 553300N 0283400E	12	1	120,000	130,000	Design capacity of 120,000 tons reported in 1981.

Soviet Petroleum-Based SCP Plants (continued)

Name	Fermentation Tanks		Capacitya		Remarks
(Alternate Names) Geographic Coordinates	Complete	Under Construction	1983	1985	
Ufa SCP Plant (Baskhir, Novoufimskiy) 550210N 0560120E	15	6	150,000	210,000	Design capacity of 180,000 tons reported in 1975.
Volograd SCP Plant (Svetloyarsk) 432810N 0444435E	20	6	200,000	260,000	Design capacity of 240,000 reported in 1975.

^aAll capacities are given in metric tons per year. Figures given are for the capacity of equipment installed. All this equipment may not be in operation. Detailed information on the construction chronologies for these plants is available on request.
